

Aerodynamics of cars

Drag reduction

Alessandro Talamelli
Johan Westin
Mekanik/KTH

1

Outline

- General remarks on drag of cars
 - How to analyse drag
- Local origins of drag
 - Individual details and their contribution to drag
- Ex. Optimisation of Opel Calibra

2

Flow around a car

Fig. 4.3 Airflow around a car and the main flow separations: a) on the front-end structure, b) on the three types of car back.

- Car=relatively bluff body ($c_D=0.25-0.45$)
- Two types of separation
 - 1) Quasi 2D wakes
 - 2) Longitudinal vortices
- Rear end determines the wake structure
 - 1) Square back
 - 2) Fast back
 - 3) Notch back
- Underbody flow and wheels
- Interactions – ground effect

3

Drag and Lift

- Drag and lift normally related (lift generates drag)
- Wing theory: Drag = profile drag (form drag + friction drag) + induced drag (induced drag from wingtip vortices)

$$c_{Di} = k \frac{c_L^2}{\Lambda} \quad \Lambda = \frac{b^2}{A_{plan}}$$

- Cars: low aspect ratio ($\Lambda \approx 0.4$)
- Interaction between tip vortices and the central flow

4

Approaches to analyse drag I

□ Examine the physical mechanisms

- Identify separation regions
- Measure pressure and wall-shear stress
- Drag obtained from surface integral

$$D = \oint p \sin \varphi dS + \oint \tau_w \cos \varphi dS$$

- Lot of experimental data needed (unrealistic)
- It is possible to find the local origins of drag

5

Approaches to analyse drag II

- Usually possible for simple bodies (see figure)
- Problem: in real cars different components interact!

6

Approaches to analyse drag III

□ Wake analysis

- Control volume approach + momentum theorem
- Energy assessment

!! Stationary wall: must subtract contribution from wall boundary layer

$$c_D A = \int_S (1 - c_{p_{tot}}) dS - \int_S \left(1 - \frac{u}{V}\right)^2 dS + \int_S \left[\left(\frac{v}{V}\right)^2 + \left(\frac{w}{V}\right)^2 \right] dS$$

- Extensive measurements needed (costly)
- Need of traversing mechanism

7

Local origins of drag - Front end I

- Local separation less pronounced suction peak - increased drag
- Small edge radius enough to reduce local drag

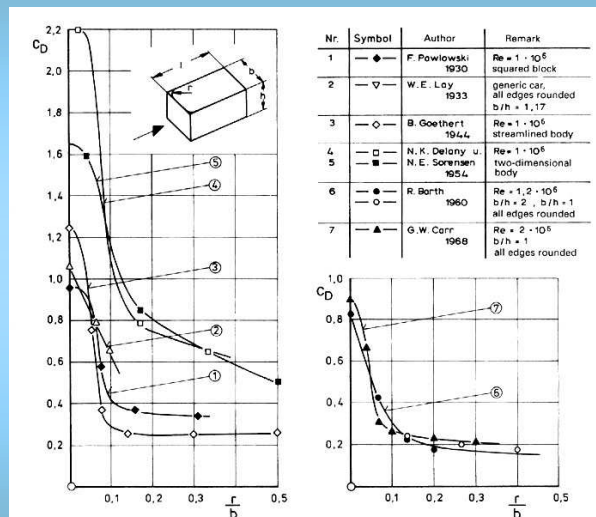

Fig. 4.26 Influence of edge radius on the drag of squared blocks, compiled from [4.29].

8

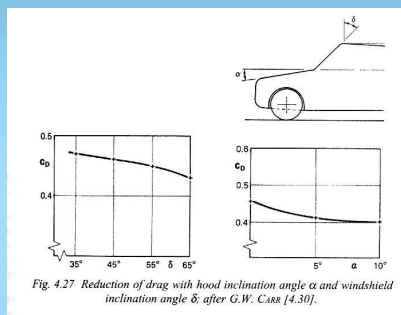

Local origins of drag - Front end II

- Optimization of the front of Golf I
- Small radii can give significant drag reduction

9

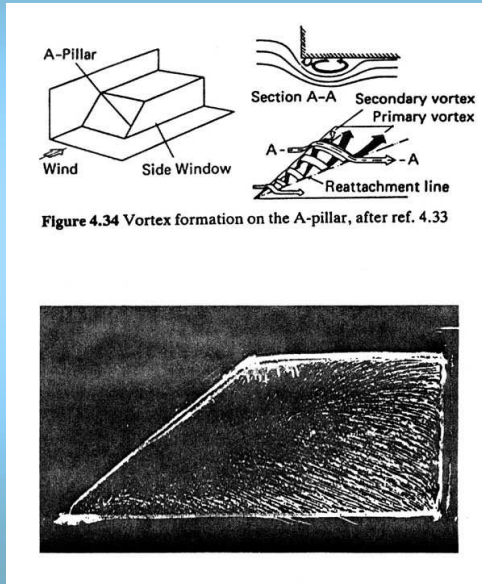

Local origins of drag - Angle of hood and wind shield I

- Drag reduction due to hood angle (α) saturates
BUT: Combination effect of hood angle & front radius!
- Increased angle of wind shield (δ) can reduce drag
- $\delta \geq 60^\circ \Rightarrow$ visibility and temperature problems
- indirect influence on drag:
 - Influence flow around A-pillar
 - Smaller suction peak at the junction to the roof

10

Local origins of drag - A-pillar

- 3D-separation (vortex)
- Wind noise
- Water and dirt deposition

11

Local origins of drag – Roof and Sides

- Mainly friction drag (flow is generally attached)
- Increased camber give larger radii =>reduced suction peaks
- Negative angle of roof => reduced wake
- Problems: large front area and/or smaller internal space

12

Local origins of drag Underbody flows

- Complex flow
- Flow angles important
- Avoid obstacles (stagnation)
- Return of cooling air can influence
- Large improvement by rear panels
- Also effect on lift

Fig. 4.12 Outward-spreading flow underneath a car.

Ahmed (1999)

13

Local origins of drag - Rear End

Mair: axisymmetric body

□ Boat tailing

- Increase base pressure
- Reduce base area
- Minor improvements by further extension of the body ($x/d > 5$)
- Squareback vehicles: lower the roof
- Flow devices (Air intakes, wings)

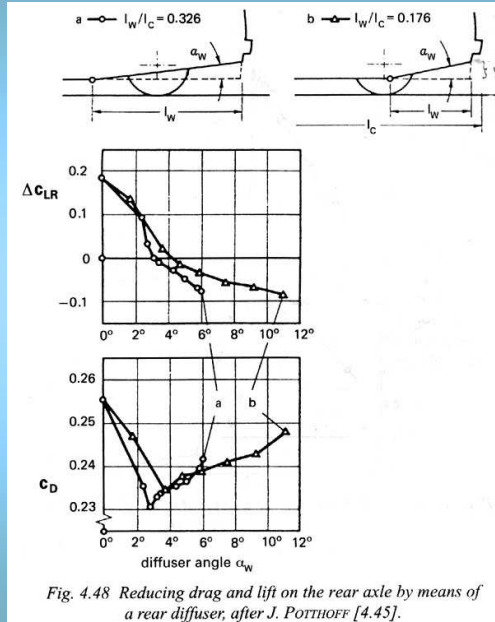

Mercedes 190
Angle ca 10°

14

Local origins of drag - Rear End II

□ Boat-tailed underbody

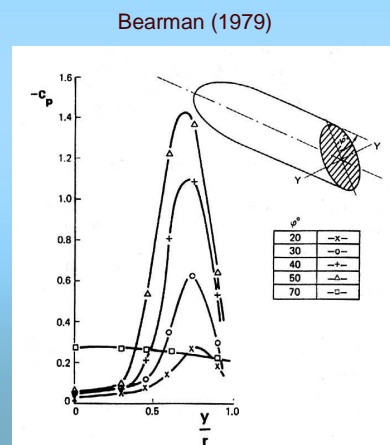

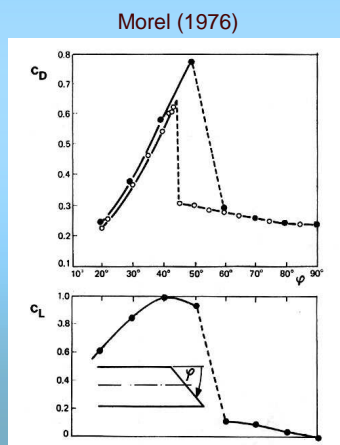

- Requires smooth underbody
- Decreased drag for moderate diffuser angles
- Reduction in lift

Local origins of drag - Rear End III

□ Fastback/squareback

- Basic experiments => understanding of rear end flow
- Drag due to strong side vortices
- Vortex break-up above critical slant angle

□ Fastback/squareback

- Prismatic body near ground (qualitatively similar results)
- Critical slant angle ca 30°
- Drag minimum at $\varphi \approx 15^\circ$ (coupé)

Morel (1976)

Bearman (1982)

□ Fastback/squareback

Development of Golf I: In-fluence of slant angle (φ)

- Bi-stable separation around critical angle ($\varphi \approx 30^\circ$)
- $\varphi > 30^\circ$: reduced drag and flow conditions similar to a square back
- $\varphi > 30^\circ$: Vortices are weaker and with opposite rotational direction than $\varphi < 30^\circ$:

Fig. 4.55 Influence of slant angle φ on drag coefficient C_d and the flow regime in the rear of the car, measured during development of the Volkswagen Golf I (Rabbit), after L.J. JASSENS and W.-H. HUCHO [4.33].

Fig. 4.8 Lateral-speed vectors and drag coefficient of a fastback, as a function of the slant angle φ , after S.R. ANZEN [4.10].

Rounded rear edges

- Previous findings based on bodies with fairly sharp edges
- Rounded side edges => no fixed separation point
- Rounded rear => optimum base height more relevant than optimum slant angle
- Also: the base height influence by sloping side edges

19

□ Notchback

- Interaction
 - quasi-2D separation
 - 3D vortices
- Several geometrical parameters
- Also influenced by
 - Radius roof-window
 - Shape of C-pillar
 - Rear end of trunk

Fig. 4.61 Flow field and drag of a notchback: a) flow pattern, schematic, b) drag coefficient c_D versus angle β , according to T. NOUZAWA, et al. [4.56].

20

Flow in the “dead water region”

- Counter rotating vortices (try to identify during PIV-lab)

Fig. 4.4 Contrarotating vortices in the dead water behind cars of different rear-end shape, after S.R. AHMED and W. BAUMERT [4.6].

Fig. 4.10 Vortex system for a fastback with: a) low drag coefficient, b) high drag coefficient with $\phi = 30^\circ$, after S.R. AHMED, et al. [4.13].

21

Sensitivity to side wind

- Wake-analysis behind a notchback (Cogotti 1986)
- Total-pressure distribution show strong influence of small yaw angles ($\beta=0, 0.5^\circ$ & 1°)
- Bi-stable flow at $\beta= 0.5^\circ$

22

Sensitivity to side wind II

- Attempt to explain asymmetric wake
 - A-pillar vortices interact with rear vortices
 - Very small yaw angles change the relative strength of A-pillar vortices
- Symmetric flow pattern unlikely on three-box config.

23

Mechanism of a 2D-diffuser

- Pressure increases as long as flow not separated
- Max diffuser length longer for small diffuser angles
- Is the analogy with a 2D diffuser really correct?
- (Can explain reduced drag, but not reduced lift)

20

24

Aspects of underbody diffuser

- Rear end underbody diffuser brings up the velocity below the car (normally reduces lift)
- Higher velocity below the car changes flow angles around the wheels
 - Reduced drag due to the wheels
 - Requires a smooth underbody to avoid drag from obstacles
- Underbody diffuser reduces the base area of the vehicle (can reduce drag)

25

Underbody shaped for downforce I

- Ferrari 360 Modena
 - “Venturi-tunnel” for max downforce
 - Smooth underbody
 - No spoilers
 - 5400 hours in wind-tunnel (source: Teknikens Värld 11/99)

Il fondo completamente
scavato facilita e regolarizza
il flusso di aria nella parte
inferiore della vettura.

26

1994

F355

1999

360 Modena

27

Wheels

- Up to 50% of the drag of a streamlined car
- Wheels are not streamlined
 - 3 vortex pairs
 - Influenced by ground and rotation
- Local flow is yawed ($\approx 15^\circ$)
 - Separation on the outer side
 - Water drops sucked out

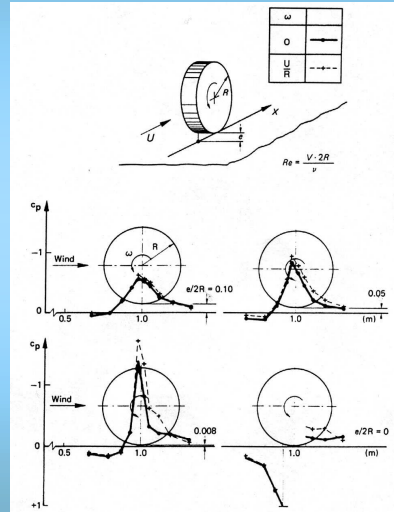

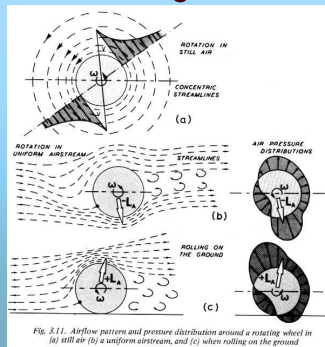

Fig. 4.72 Flow pattern of a wheel rolling on the ground, after E. MERCKER and H. BERNEBURG [4.61].

28

Wheels (contd)

- Force on a rotating wheel changes sign when contact with ground
- Lift force due to wheel rotation for a free-standing wheel

29

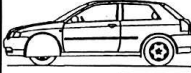

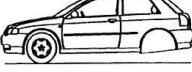

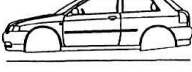

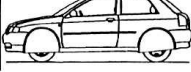

Wheels (contd)

- How does the flow in the wheel-housings look like?
- Wheel-housings
 - Smaller=better
 - Both lift and drag reduced
 - Largest effect on lift (see e.g. Cogotti 1983)

30

Influence of wheels on Audi A3

configurations without wheels (without wheels and wheel arches covered)	ΔC_D	C_D	difference <- - - ->	C_D	ΔC_D	conf. with wheel arches covered (only wheel arches covered)
	Ref.					
	Ref.	0.316	0.000	0.316	Ref.	
	0.042	0.274	0.029	0.303	0.013	
	0.057	0.259	0.051	0.310	0.006	
	0.102	0.214	0.080	0.294	0.022	

- 30-35% of drag due to wheels + wheel arches
- Ca 25% only due to wheels

From Pfadenhauer,
Wickern & Zwicker (1996)

31

Spoilers

□ Front spoiler

- +Reduced drag
- +Reduced front axle lift
- +Improved cooling air flow
- Reduced flow rate under the car
- Low pressure region behind the spoiler
- Optimization needed

Fig. 4.78 Velocity distribution underneath a car with and without front spoiler, after C. KRAMER, et al. [4.63].

Hucho (1998)

□ Rear spoiler

- + Reduced drag (sometimes)
- + Reduce rear axle lift
- Higher c_p in front of the spoiler
- Increased spoiler height increases the lift, but also drag

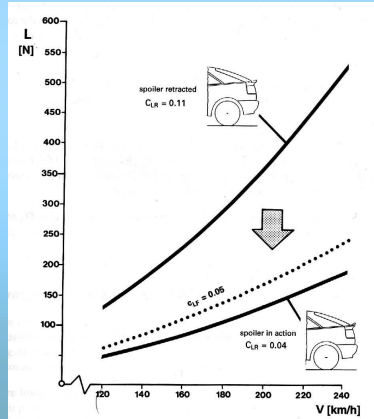

Fig. 4.91 Change in pressure distribution around the Volkswagen Corrado with the addition of a retractable rear spoiler, after H. SCORICIA and R. HORN [4.72].

33

Miscellaneous

- Cooling air flow: $\Delta c_D \approx 0.02-0.06$
- Side mirrors: $\Delta c_D \approx 0.01$
- Antenna: $\Delta c_D \approx 0.001$
- Roof racks: up to 30-40% increase in c_D
- Ski box: Why are they shaped in this way??

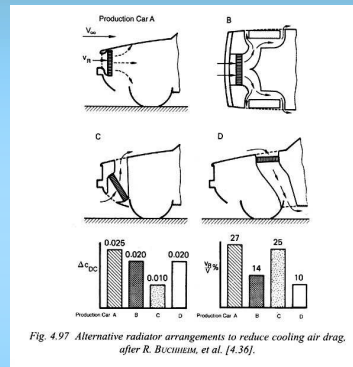

Fig. 4.97 Alternative radiator arrangements to reduce cooling air drag, after R. BUCCISUM, et al. [4.36].

34

Potential fields for drag reduction

- More focus on underbody and wheels
- Active reduction of the dead-water region
 - Base bleed
- Separation control
 - Boundary layer suction?

35

Discrepancies in c_D

- Different c_D depending on equipment
 - Tire width
 - Engine type (cooling air flow)
 - Ground clearance (load dependent)
 - Angle of attack (load dependent)
 - Additional spoilers etc.
- Official c_D values “corrected”

36

Aerodynamic optimization of Opel Calibra

- Front spoiler height optimization
 - Determined by minimum ground clearance

From Emmelmann et al (1990)

37

- Rear end optimization (1:5 scale model)
- Rear end tapering
- Decklid height optimization
 - Interdependent effect of decklid height and rear end tapering
 - Large number of parameter tests needed

Fig.10: The influence of rear end taper on the drag coefficient.

Fig.11: The influence of decklid height on the drag coefficient.

38

- $c_D \approx 0.28$ at this time
- Wake analysis (total pressure) and flow vis.
 - No noticeable tip vortices
 - “Ears” due to A-pillars
 - Wide wake close to ground
 - 30° flow angle at front wheels
- Drag reduction by
 - Reduced spoiler height in the centre
 - Increased spoiler height in front of wheels
 - Lower the door sills

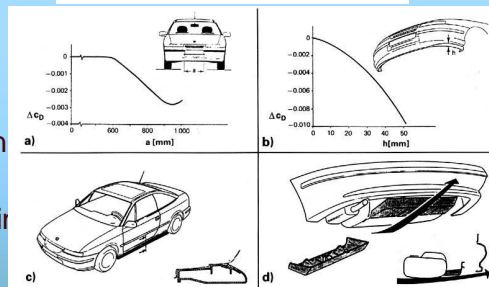

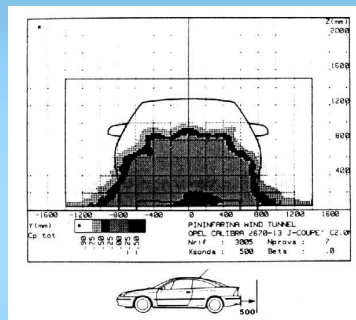

Fig. 4.82 Spoiler development for the Opel Calibra: a) optimum central cutout in the spoiler, b) extended spoiler “corners,” c) lowering the door sill, d) improving rear diffuser, after H.-J. EMMELMANN, et al. [4.18].

Before ($c_D \approx 0.28$)

After ($c_D \approx 0.26$)

- Further aerodynamical development
 - Anti-contamination lips
 - Cooling air inlets ($\Delta c_D = 0.014$ for air passing through front end)
